Recap: Survival Identities

In survival analysis we consider the random variable
"*X*: Time until event"
x = 0.1 weeks, 2.3 weeks…

We express our knowledge about the distribution of *X* in any of these functions. Knowing any single function we can derive all other via the **Survival Identities**.

f(*x*): Density function
The relative likelihood of experiencing the event around time *x*.

h(*x*): Hazard function
The instantaneous rate of new events at time *x* among those who did not experience the event yet.

$\mathbf{h(x) = \lim_{h \to 0} P(x \le X < x+h | X \ge x)/h}$

$F(x)=\int_0^x f(x)\,dx$

$S(x)=\int_x^{Inf} f(x)\,dx$

$h(x)=- S'(x)/S(x)$

F(*x*): Distribution function
aka Cumulative function
The probability of experiencing the event until time *x*.
F(*x*) = P(*X*≤*x*)

S(x)=1-F(x)

S(*x*): Survival function

The probability of *not* experiencing the event until time *x*.
S(*x*) = P(*X*>*x*)

$H(x) = \int_0^x h(x)\,dx$

H(x) = -log S(x)

H(*x*): Cumulative Hazard
The integral of h(x).

S(x) = exp(-H(x))

What Does Survival Data Look Like?

In survival analysis we consider the random variable
"*X*: Time until event"
x = 0.1 month, 2.3 months…

Who? 8 breast cancer patients
Start of observation? Cancer diagnosis
Event of interest? Death
Time unit? Months
End of observation? 10 years follow up

Recap

For the Kaplan-Meier Estimator read

Klein & Moeschberger (2003). Survival Analysis. pp. 91–93.

Homework

Using R, produce a Kaplan-Meier plot related to the topic of your eventual seminar paper (“Hausarbeit”).

You don’t need to have all the data for your topic yet, but you need to find “some” related data. Be prepared to present your plot to the group. Think about study time start and end, event of interest, and censoring. You may compare multiple groups, but a KM-plot for a single group is fine as well.
